Background

- Tissue acquisition in the brain is highly invasive be associated with substantial morbidity. Theref repeated attempts at tissue acquisition at times recurrence are often not possible.
- Additionally, sequencing of a single small specim tumor tissue may underrepresent the molecular heterogeneity of the tumor.
- Further, the blood-brain barrier limits the effication blood-based liquid biopsy in brain tumor patien preventing tumor materials, such as circulating DNA (ctDNA), from entering systemic circulation
- Cerebrospinal fluid (CSF)-based liquid biopsy is a promising alternative as collection is less invasiv may better represent the genomic profile of the due to intimate contact between CSF and tumor However, datasets with contemporaneously coll and tissue to support this claim have been lackir
- To evaluate the performance of CSF next-general sequencing (NGS), we conducted a pilot study in with GBM undergoing resection for suspected re following first-line chemoradiotherapy.

Methods

- CSF and tissue were collected from 18 patients.
- CSF samples were collected directly from the ver space intraoperatively and either transferred to Blood Collection Tubes and shipped to Tempus (Chicago, IL) or processed in-house by two step centrifugation and shipped at -80 °C.
- Paired CSF and tissue samples were sequenced Tempus xF and xT NGS assays:

• Tissue, 648 genes; CSF, 105 genes Clinically meaningful genes* are those with variant are potentially targetable using off-label or clinic options, exhibit prognostic value, or may predict response or resistance to specific treatments.

Targeted next-generation sequencing (NGS) of temporally matched cerebrospinal fluid (CSF) and tumor tissue in patients with recurrent glioblastoma (GBM)

s. rentricular	Figure 1. CSF/tissue pairs were sequenced successfully for 10 patients. Among 38 clinically meaningful genes*, 38 biologically relevant somatic variants were detected; 15 (39.5%) in both tissue and CSF, 13 (34.2%) solely in CSF and 10 solely in tissue (26.3%). Two different EGFR mutations were detected for subject 1, and 2 different NF1 mutations found for subjects 3 and 7.

Figure 3. Somatic hypermutation was detected in one patient. Of the 82 variants detected in this patient, 15 (18.3%) were identified in both tissue and CSF, 15 (18.3%) were identified only in the tissue, and 52 (63.2%) were identified only in the CSF. *VUS=variant of uncertain significance

- comprehensive tumor profile.
- CSF-based liquid biopsy.

Conclusions

• CSF NGS detects clinically meaningful variants at a substantial rate and frequently identifies mutations not detected by matched tissue NGS.

• These results suggest that CSF may be a suitable source material for tumor profiling, overcoming the limitations of tissue, and may also provide a more

• Future studies may aim to identify pre-analytical variables that influence the performance of

• We would like to acknowledge the Steven Elek III Fund and the Tara Miller Fund that
