INTRODUCTION

- Recent advanced BTC clinical trials reported a ~1.5 mo overall survival (OS) benefit with 1L immunotherapy (ICI) added to gemcitabine + cisplatin (G+C)
- Real world (rw) confirmation of 1L ICI benefit is limited and predictive ICI biomarkers are lacking
- We investigated the relationship between pt outcomes, BTC subtype, immunologic phenotype, and genomic alterations (gAlt) in patients with BTC treated with 1L G+C+ICI

METHODS

We used Tempus Lens to analyze a cohort of de-identified patients with BTC sequenced with xT (DNA seq; 596-648 genes) ± xR (whole-transcriptome RNA-seq). Patients were stratified by subtype (intrahepatic, iCCA; extrahepatic, eCCA; gallbladder, GBC), median %CD8 T cells (%CD8T) High (H)/Low (L), and gAlt: *IDH1*, *KRAS*, *TP53*, *ARID1A*, DDR (23 genes) alt, *FGFR2* fusions and MTAP loss. Immunologic phenotype was assessed by TMB (m/MB). Immune infiltration was estimated by quanTIseq (RNA). rwOS was defined as time from the start of 1L G+C±ICI to death from any cause. Median rwOS (mOS) was estimated using the Kaplan-Meier method and hazard ratios (HR) estimated with Cox proportional hazard models.

SUMMARY

- The real world study shows similar rwOS with G+C+ICI in BTC and the gAlts in FGFR2, DDR, TP53 and KRAS genes appeared prognostic
- While there was a modest trend towards improved OS in patients with GBC, a cancer type with a higher proportion of CD8 T cells, the results did not reach statistical significance
- Future immunogenomic analysis in clinical trials is warranted to identify additional prognostic and predictive markers

RESULTS

Figure 1. Somatic landscape overall BTC and actionable alterations across subtypes

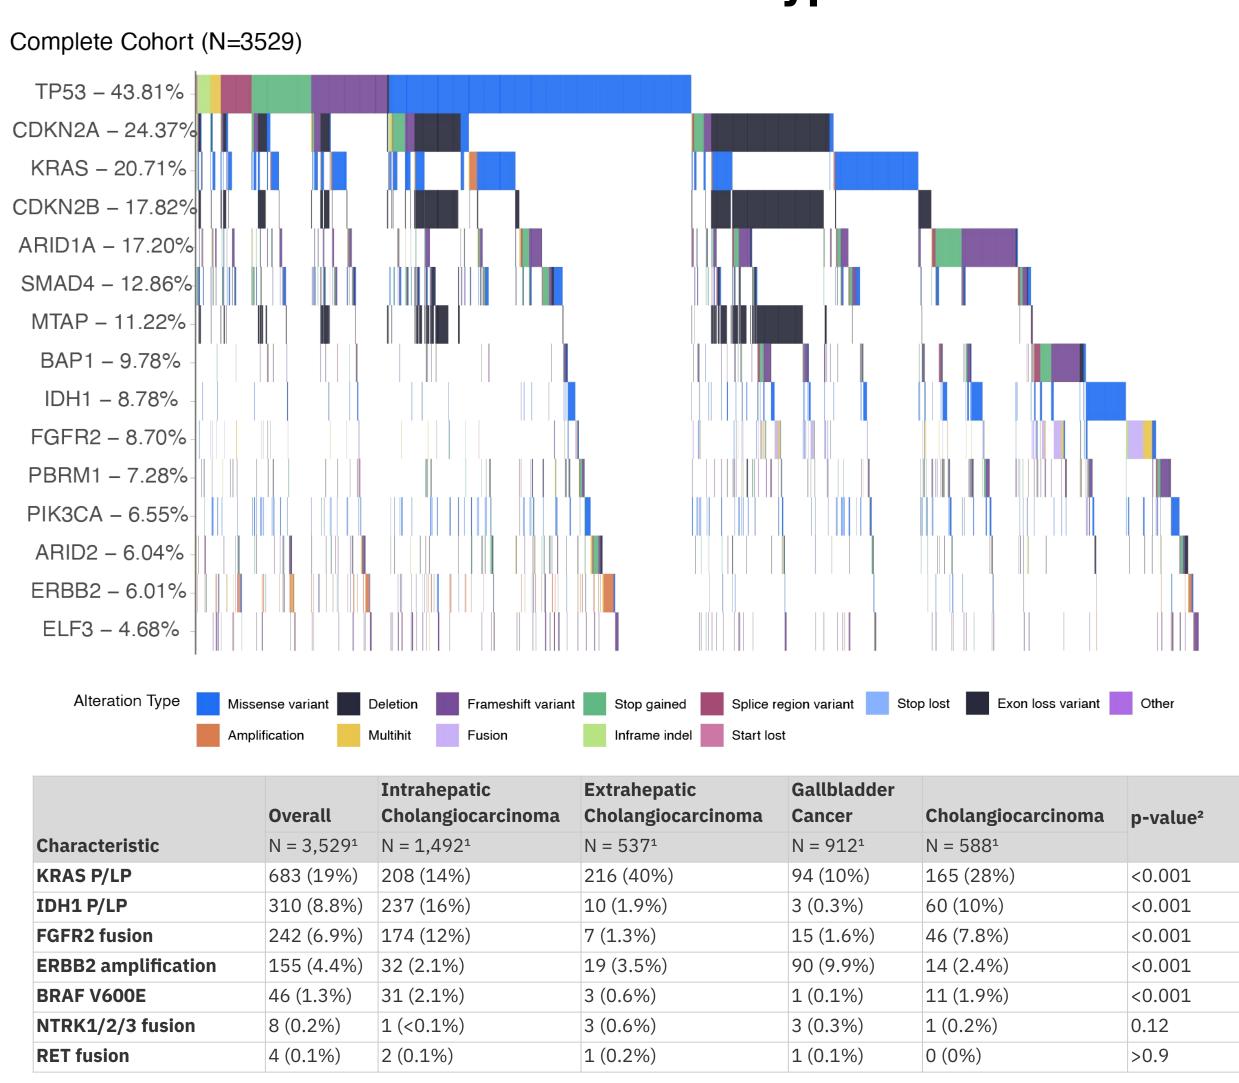

Figure 1. The 15 most commonly altered genes across all patients are shown. The table shows the prevalence of targetable drivers across BTC subtypes.

Figure 2. CD8T cell proportions across BTC subtypes

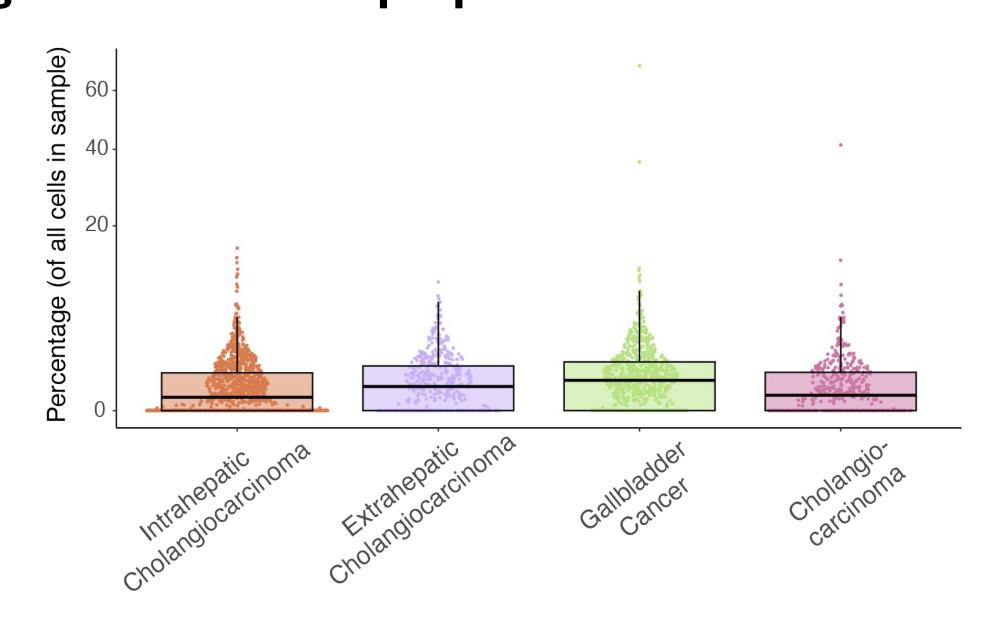

Figure 2. Patients with GBC had the highest proportion of CD8T cells and patients with iCCA had the lowest proportion of CD8T cells (p<0.001).

Figure 3. OS in the BTC patient population treated with G+C+ICI

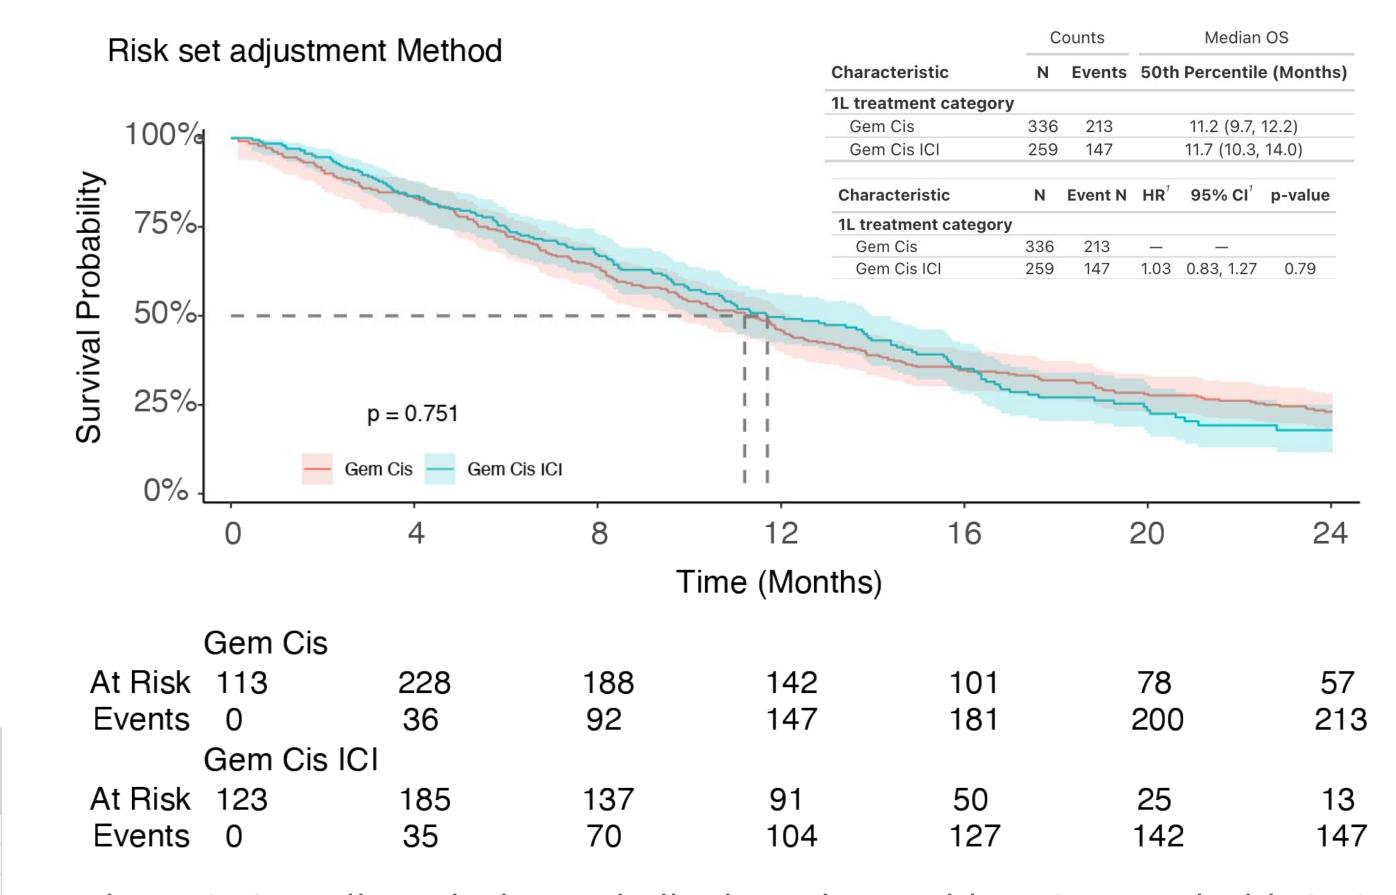

Figure 3. Overall survival was similar in patients with BTC treated with G+C vs G+C+ICI.

Figure 4. OS stratified by BTC subtype

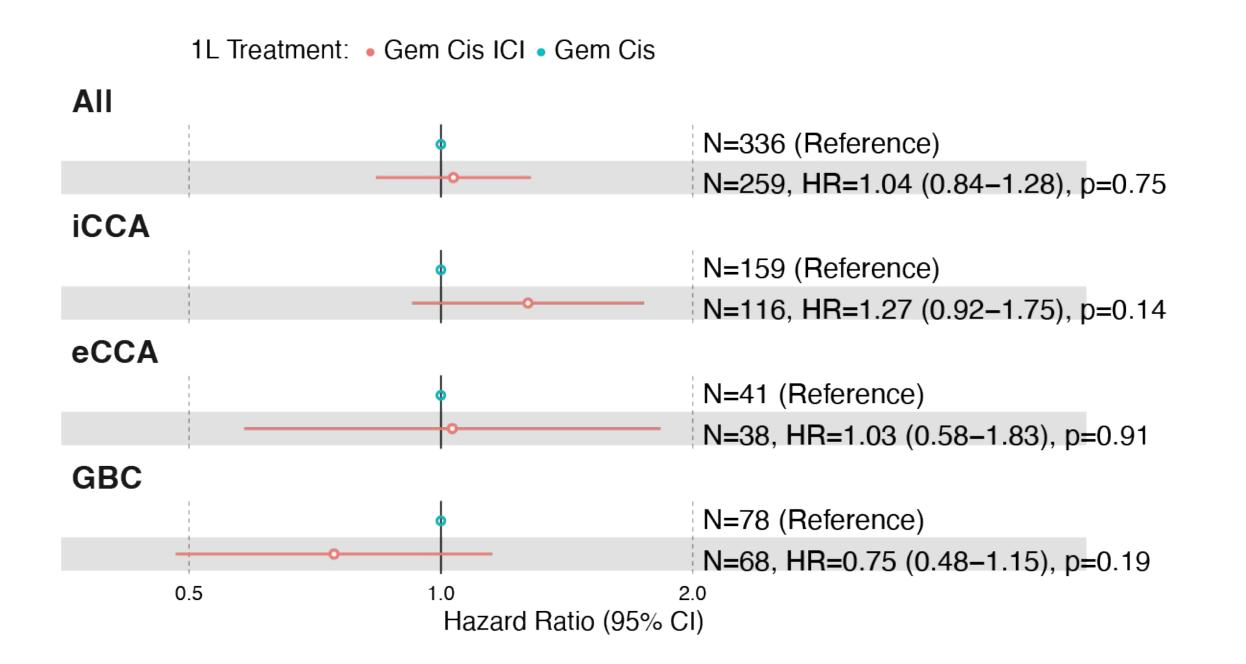

Figure 4. While there was a modest trend towards improved OS in patients with GBC, no subtype showed a statistically significant benefit from G+C+ICI compared to G+C

Figure 5. OS stratified by CD8T cell proportions

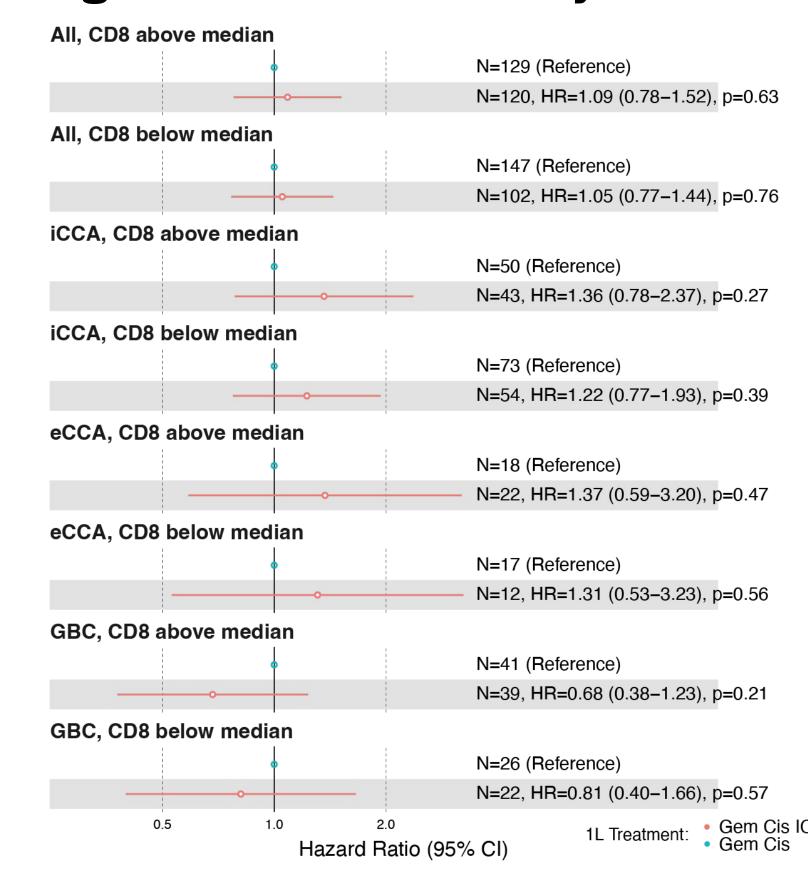

Figure 5. Higher CD8T cell proportions did not enrich for G+C+ICI benefit. However, there was a non statistically significant trend towards improved OS in patients with GBC and CD8T cells above the median.

Figure 6. OS stratified genomic alterations
